**ABSTRACT**

A spectral content of a baseband waveform is varied and a measure of the baseband waveform whose spectral content has been varied is used by a transmitter in order to convey information. According to embodiments of inventive concepts, a set of frequencies that is used to provide spectral content to the baseband waveform is varied. In some embodiments, the spectral content comprises non-contiguous first and second frequency intervals wherein a third frequency interval that is between the first and second frequency intervals remains substantially devoid of providing spectral content in order to reduce or avoid interference. In other embodiments, the spectral content that is varied comprises a bandwidth that is varied. The inventive concepts are relevant to 4G LTE carrier aggregation systems/methods and/or other aspects of 4G LTE. Various transmitter/receiver embodiments are disclosed including direct synthesis transmitter/receiver embodiments.

## FIELD

This invention relates to communications systems and methods, and more specifically to wireless communications systems and methods.

## BACKGROUND

Wireless communications systems and methods are increasingly being used for voice, data and/or multimedia communications. As the use of these systems/methods continues to increase, available bandwidths may limit the ability to transmit voice/data/multimedia content.

## SUMMARY

Embodiments are provided wherein a spectral content of a baseband waveform that is transmitted by a transmitter in order to convey information is varied. According to additional embodiments, a set of frequencies that is used to provide

2

spectral content to the baseband waveform is also varied and comprises non-contiguous first and second frequency intervals wherein a third frequency interval that is between the first and second frequency intervals remains substantially devoid of frequency content in order to reduce or avoid interference. The invention is relevant to 4G LTE carrier aggregation systems/methods and/or other aspects of 4G LTE. Various transmitter/receiver embodiments are disclosed including direct synthesis transmitter/receiver embodiments.

## BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic illustration of functions of a transmitter according to embodiments of the present invention.

FIG. 2 is a schematic illustration of further functions of a transmitter according to further embodiments of the present invention.

FIG. 3 is a schematic illustration of waveform generation according to additional embodiments of the present invention.

FIG. 4 is a schematic illustration of further functions of a transmitter according to further embodiments of the present invention.

FIG. 5 is a schematic illustration of additional functions of a transmitter according to additional embodiments of the present invention.

FIG. 6 is a schematic illustration of functions of a receiver according to embodiments of the present invention.

FIG. 7 is a schematic illustration of further functions of a transmitter according to further embodiments of the present invention.

FIG. 8 is a schematic illustration of spectrum used by a transmitter according to embodiments of the present invention.

FIG. 9 is a schematic illustration of further functions of a receiver according to further embodiments of the present invention.

FIG. 10 is a schematic illustration of a communications system based upon one or more transmitters and one or more receivers according to further embodiments of the present invention.

FIGS. 11 through 14 illustrate functions of a receiver according to further embodiments of the present invention.

FIG. 15 is a schematic illustration of further functions of a transmitter and receiver according to further embodiments of the present invention.

## DETAILED DESCRIPTION

A wireless communications system configured for Low Probability of Intercept (LPI), Low Probability of Detection (LPD) and/or Low Probability of Exploitation (LPE) communications may use waveforms substantially void of a cyclostationary signature to improve a LPI/LPD/LPE property. It is known that, in general, a set of M independent “seed” waveforms that satisfy a time-bandwidth constraint may be used via a Gram-Schmidt Orthogonalization (GSO) procedure to generate M orthonormal functions. In accordance with exemplary embodiments of the present invention, the M seed waveforms may, for example, be chosen from a band-limited Gaussian-distributed process (such as, for example, Gaussian-distributed pseudo-random noise) and may be used to generate, via an orthogonalization operation, such as, for example, a GSO, a corresponding set of M Gaussian-distributed orthonormal functions substantially void of a cyclostationary property. The set of M Gaussian-distributed orthonormal functions may be used in a communications

system to define a signaling alphabet of a transmitter of the communications system (and a corresponding matched filter bank of a receiver of the communications system) to thereby reduce or eliminate a cyclostationary signature of a transmitted communications waveform and thus increase a covertness measure of the communications system. The set of  $M$  Gaussian-distributed orthonormal functions may be updated, modified and/or changed as often as necessary to further increase and/or maximize a covertness measure of the communications system. A receiver of the communications system may be equipped with substantially the same algorithm(s) that are used by the transmitter of the communications system and the receiver may be substantially synchronized with the transmitter to thereby re-create and use at the receiver the  $M$  Gaussian-distributed orthonormal functions for detection of communications information. The set of  $M$  orthonormal functions may, in some embodiments, be a set of orthogonal but not necessarily orthonormal functions. In further embodiments, the set of  $M$  orthonormal functions may be non-Gaussian distributed and may be, for example, uniformly distributed, Rayleigh distributed and/or distributed in accordance with any other known (continuous and/or discrete) and/or arbitrary distribution. In still further embodiments of the invention, different functions/elements of an  $M$ -ary orthonormal and/or orthogonal signaling alphabet may be differently distributed.

Known systems and/or methods of LPI/LPD/LPE and/or Jam Resistant (JR) Burst Communications (BURSTCOMM) may combine, in general, hybrid spread-spectrum waveforms comprising Frequency-Hopping (FH), Direct Sequence Pseudo-Noise (DSPN) spreading and/or Time-Hopping (TH) to increase covertness and/or resistance to jamming. Transmitting a FH/DSPN spread-spectrum waveform in pseudo-random short bursts using, for example, a TH technique, may, for example, reduce an interceptor's ability to integrate sufficient energy to trigger a detectability threshold associated with a radiometer that the interceptor may be using as a means of signal detection/identification. It is known that a radiometric approach to signal detection/identification may yield a suboptimum and/or unsatisfactory performance measure when attempting to detect/identify/exploit a FH/DSPN/TH spread-spectrum communications signal in a changing noise and/or interference environment. An analysis by Gardner, however, has shown that a cyclic feature of a communications waveform may advantageously be exploited by an interceptor even when a radiometric-based method fails to detect the communications waveform due to a background noise/interference level and/or a signal energy reaching the interceptor's receiver being insufficient over the interceptor's radiometric integration time (see W. A. Gardner, "Signal Interception: A Unifying Theoretical Framework for Feature Detection," IEEE Transactions on Communications, Vol. 36, No. 8, August 1988). It is, therefore, desirable to be able to communicate information using waveforms that do not substantially include a cyclostationary signature in order to further reduce the probability of intercept/detection/exploitation of a communications system/waveform that is intended for LPI/LPD/LPE communications.

There are at least two potential advantages associated with signal detection, identification, interception and/or exploitation based on cyclic spectral analysis compared with the energy detection (radiometric) method: (1) A cyclic signal feature (i.e., chip rate and/or symbol rate) may be discretely distributed even if a signal has a continuous distribution in a power spectrum. This implies that signals that may have overlapping and/or interfering features in a power spectrum may have a non-overlapping and distinguishable feature in

terms of a cyclic characteristic. (2) A cyclic signal feature associated with a signal's cyclostationary property, may be identified via a "cyclic periodogram." The cyclic periodogram of a signal is a quantity that may be evaluated from time-domain samples of the signal, a frequency-domain mapping such as, for example, a Fast Fourier Transform (FFT), and/or discrete autocorrelation operations. Since very large point FFTs and/or autocorrelation operations may be implemented using Very Large Scale Integration (VLSI) technologies, Digital Signal Processors (DSPs) and/or other modern technologies, a receiver of an interceptor may be configured to perform signal Detection, Identification, Interception and/or Exploitation (D/I/I/E) based on cyclic feature detection processing.

Given the potential limitation(s) of the radiometric approach and the potential advantage(s) of cyclic feature detection technique(s) it is reasonable to expect that a sophisticated interceptor may be equipped with a receiver based on cyclic feature detection processing. It is, therefore, of potential interest and potential importance to develop communications systems capable of communicating information void of cyclostationary properties/signatures to thereby render cyclic feature detection processing by an interceptor substantially ineffective.

FIG. 1 illustrates embodiments of generating a communications alphabet comprising  $M$  distinct pseudo-random, non-cyclostationary, orthogonal and/or orthonormal waveforms. As illustrated in FIG. 1, responsive to a "key" input (such as, for example, a TRANsmissions SECurity (TRANSEC), a COMMunications SECurity (COMMSEC) and/or any other key input), a Pseudo-Random Waveform Generator (PRWG) may be used to generate a set of  $M$  distinct pseudo-random waveforms, which may, according to some embodiments of the invention, represent  $M$  ensemble elements of a Gaussian-distributed random process. The  $M$  distinct pseudo-random waveforms (e.g., the  $M$  ensemble elements) may be denoted as  $\{S(t)\} = \{S_1(t), S_2(t), S_M(t)\}; 0 \leq t \leq \tau$ . The set of waveforms  $\{S(t)\}$  may be a band-limited set of waveforms having a one-sided bandwidth less than or equal to  $B$  Hz. As such, a number of distinct orthogonal and/or orthonormal waveforms that may be generated from the set  $\{SW\}$  may, in accordance with established Theorems, be upper-bounded by  $CTB$ , where  $C \geq 2$  (see, for example, P. M. Dollard, "On the time-bandwidth concentration of signal functions forming given geometric vector configurations," IEEE Transactions on Information Theory, IT-10, pp. 328-338, October 1964; also see H. J. Landau and H. O. Pollak, "Prolate spheroidal wave functions, Fourier analysis and uncertainty—III: The dimension of the space of essentially time-and band-limited signals," BSTJ, 41, pp. 1295-1336, July 1962).

In accordance with some embodiments of the present invention, the  $j^{th}$  element of the set of waveforms  $\{S(t)\}$ ,  $S_j(t)$ ;  $j=1, 2, \dots, M$ ; may be generated by a respective  $j^{th}$  PRWG in response to a respective  $j^{th}$  key input, as illustrated in FIG. 2. In some embodiments according to FIG. 2, each of the PRWG is the same PRWG and each key differs relative to each other key. In other embodiments, each key is the same key and each PRWG differs relative to each other PRWG. In further embodiments of FIG. 2, each key differs relative to each other key and each PRWG also differs relative to each other PRWG. Other combinations and subcombinations of these embodiments may be provided. In still other embodiments, a single PRWG and a single key may be used to generate a "long" waveform  $S_L(t)$  which may be segmented into  $M$  overlapping and/or non-overlapping components to form a set of waveforms  $\{S(t)\}$ , as illustrated in FIG. 3. In some embodiments, a new set of waveforms  $\{S(t)\}$  may be formed periodically,

non-periodically, periodically over certain periods of time and/or periodically but with a jitter imposed on a periodicity interval, responsive one or more Time-of-Day (TOD) value(s), as may, for example, be derived from processing of Global Positioning System (GPS) signals, and/or following the transmission of a measure of at least one of the elements of  $\{S(t)\}$ . In some embodiments, a processor may be operatively configured as a background operation, generating new sets of waveforms  $\{S(t)\}$ , and storing the new sets of waveforms  $\{S(t)\}$  in memory to be accessed and used as needed. In further embodiments, a used set of waveforms  $\{S(t)\}$  may be discarded and not used again, whereas in other embodiments, a used set of waveforms  $\{S(t)\}$  may be placed in memory to be used again at a later time. In some embodiments, some sets of waveforms  $\{S(t)\}$  are used once and then discarded, other sets of waveforms  $\{S(t)\}$  are not used at all, and still other sets of waveforms  $\{S(t)\}$  are used more than once. Finally, in some embodiments, the waveform duration  $T$  and/or the waveform bandwidth  $B$  may vary between at least two sets of waveforms and/or between two elements of a given set of waveforms.

Still referring to FIG. 1, the set of substantially continuous-time waveforms  $\{S(t)\}=\{S_1(t), S_2(t), S_M(t)\}; 0 \leq t \leq \tau$ ; may be transformed from a substantially continuous-time representation to a substantially discrete-time representation using, for example, one or more Analog-to-Digital (A/D) converters and/or one or more Sample-and-Hold (S/H) circuits, to generate a corresponding substantially discrete-time set of waveforms  $\{S(nT)\}=\{S_1(nT), S_2(nT), S_M(nT)\}; n=1, 2, \dots, N; nT \leq \tau$ . A Gram-Schmidt orthogonalizer and/or orthonormalizer and/or any other orthogonalizer and/or orthonormalizer, may then be used, as illustrated in FIG. 1, to generate a set of waveforms  $\{U(nT)\}=\{U_1(nT), U_2(nT), U_M(nT)\}; n=1, 2, \dots, N; nT \leq \tau$  that are orthogonal and/or orthonormal to one another. The GSO and/or other orthogonalization and/or orthonormalization procedure(s) are known to those skilled in the art and need not be described further herein (see, for example, Simon Haykin, "Adaptive Filter Theory," at 173, 301, 497; 1986 by Prentice-Hall; and Bernard Widrow and Samuel D. Stearns "Adaptive Signal Processing," at 183; 1985 by Prentice-Hall, Inc.). It will be understood that the sampling interval  $T$  may be chosen in accordance with Nyquist sampling theory to thereby preserve by the discrete-time waveforms  $\{S(nT)\}$  substantially all of the information contained in the continuous-time waveforms  $\{S(t)\}$ . It will also be understood that, in some embodiments of the invention, the sampling interval  $T$  may be allowed to vary over the duration  $\tau$  of one waveform, between different waveforms of a given set of waveforms and/or between different sets of waveforms. Furthermore, the waveform duration  $\tau$  may be allowed to vary, in some embodiments, between different waveforms of a given set of waveforms and/or between different sets of waveforms.

The set  $\{U(nT)\}=\{U_1(nT), U_2(nT), U_M(nT)\}; n=1, 2, \dots, N; NT \leq \tau$ , may be used, in some embodiments of the present invention, to define an M-ary pseudo-random and non-cyclostationary alphabet. As illustrated in FIG. 4, an information symbol  $I_k$ , occurring at a discrete time  $k$  (for example, at  $t=k\tau$  or, more generally, if the discrete time epochs/intervals are variable, at  $t=\tau_k$ ), and having one of  $M$  possible information values,  $\{I_1, I_2, \dots, I_M\}$ , may be mapped onto one of the  $M$  waveforms of the M-ary alphabet  $\{U_1(nT), U_2(nT), U_M(nT)\}; n=1, 2, \dots, N; NT \leq \tau$ . For example, in some embodiments, if  $I_k=I_2$ , then during the  $k^{th}$  signaling interval the waveform  $U_2(nT)$  may be transmitted;  $n=1, 2, \dots, N; NT \leq \tau$ . It will be understood that transmitting the waveform  $U_2(nT)$  comprises transmitting substantially all of the elements (samples) of the waveform  $U_2(nT)$  wherein substan-

tially all of the elements (samples) of the waveform  $U_2(nT)$  means transmitting  $U_2(T), U_2(2T), \dots$ , and  $U_2(NT)$ . Furthermore, it will be understood that any unambiguous mapping between the  $M$  possible information values of  $I_k$  and the  $M$  distinct waveforms of the M-ary alphabet,  $\{U_1(nT), U_2(nT), U_M(nT)\}$ , may be used to communicate information to a receiver (destination) provided that the receiver also has knowledge of the mapping. It will also be appreciated that the ordering or indexing of the alphabet elements and the unambiguous mapping between the  $M$  possible information values of  $I_k$  and the  $M$  distinct waveforms of the M-ary alphabet may be arbitrary, as long as both transmitter (source) and receiver (destination) have knowledge of the ordering and mapping.

In some embodiments of the invention, the information symbol  $I_k$ , may be constrained to only two possible values (binary system). In such embodiments of the invention, the M-ary alphabet may be a binary ( $M=2$ ) alphabet comprising only two elements, such as, for example,  $\{U_1(nT), U_2(nT)\}$ . In other embodiments of the invention, while an information symbol,  $I_k$ , is allowed to take on one of  $M$  distinct values ( $M \geq 2$ ) the alphabet comprises more than  $M$  distinct orthogonal/orthonormal waveforms  $\{U_1(nT), U_2(nT), U_L(nT)\}; L > M$  to thereby increase a distance between a set of  $M$  alphabet elements that are chosen and used to communicate information and thus allow an improvement of a communications performance measure such as, for example, an error rate, a propagation distance and/or a transmitted power level. It will be understood that in some embodiments, the number of distinct values that may be made available to an information symbol to thereby allow the information symbol to communicate one or more bits of information, may be reduced or increased responsive to a channel state such as, for example an attenuation, a propagation distance and/or an interference level. In further embodiments, the number of distinct elements comprising the orthogonal/orthonormal alphabet may also change responsive to a channel state. In some embodiments, as a number of information symbol states (values) decreases, a number of distinct elements comprising the orthogonal/orthonormal alphabet increases.

It will be understood that at least some conventional transmitter functions comprising, for example, Forward Error Correction (FEC) encoding, interleaving, data repetition, filtering, amplification, modulation, frequency translation, scrambling, frequency hopping, etc., although not shown in FIGS. 1 through 4, may also be used in some embodiments of the present invention to define an overall transmitter chain. At least some of these conventional transmitter functions may be used, in some embodiments, in combination with at least some of the signal processing functions of FIGS. 1 through 4, to specify an overall transmitter signal processing chain. For example, an information bit sequence may be FEC encoded using, for example, a convolutional encoder, interleaved and/or bit-to-symbol converted to define a sequence of information symbols,  $\{I_k\}$ . The sequence of information symbols,  $\{I_k\}$ , may then be mapped onto a waveform sequence  $\{U_k\}$ , as illustrated in FIG. 4. At least some, and in some embodiments all, of the elements of the waveform sequence  $\{U_k\}$  may then be repeated, at least once, to increase a redundancy measure, interleaved, filtered, frequency translated, amplified and/or frequency-hopped, for example, (not necessarily in that order) prior to being radiated by an antenna of the transmitter. An exemplary embodiment of a transmitter comprising conventional signal functions in combination with at least some of the signal processing functions of FIGS. 1 through 4, to specify an overall transmitter signal processing chain, is illustrated in FIG. 5.

A receiver (destination) that is configured to receive communications information from a transmitter (source) comprising functions of FIGS. 1 through 4, may advantageously be equipped with sufficient information to generate a matched filter bank corresponding (and responsive) to the M-ary alphabet  $\{U_1(nT), U_2(nT), U_M(nT)\}$  of FIG. 4. Such a receiver may be substantially synchronized with one or more transmitters using, for example, GPS signal processing. Substantial relative synchronism between a receiver and at least one transmitter may be used and/or may be essential in order to reliably generate and/or update at the receiver the M-ary alphabet functions  $\{U_k(nT), U_2(nT), U_M(nT)\}$  and/or the matched filter bank in coordination with one or more transmitters (responsively to TOD and/or key values) to thereby provide the receiver with substantial optimum reception capability. In some embodiments of the invention, all transmitters and receivers are substantially synchronized using GPS signal processing. It will be understood that a receiver may be provided with the appropriate key sequence(s) (e.g., TRANSEC) and the appropriate signal processing algorithms to thereby responsively form and/or update the M-ary alphabet functions and/or the matched filter bank. It will also be understood that a receiver may also be configured with an inverse of conventional transmitter functions that may be used by a transmitter. For example, if, in some embodiments, a transmitter is configured with scrambling, interleaving of data and frequency hopping, then a receiver may be configured with the inverse operations of de-scrambling, de-interleaving of data and frequency de-hopping. An exemplary embodiment of a receiver, which may correspond to the exemplary transmitter embodiment of FIG. 5, is illustrated in FIG. 6.

FIG. 7 illustrates elements of a communications transmitter according to further embodiments of the invention. As shown in FIG. 7, following conventional operations of Forward Error Correction (FEC) encoding, bit interleaving and bit-to-symbol conversion (performed on an input bit sequence  $\{b\}$  to thereby form an information symbol sequence  $\{I_k\}$ ), the information symbol sequence  $\{I_k\}$  is mapped onto a non-cyclostationary waveform sequence  $\{U_k(nT)\}$  using a first M-ary non-cyclostationary orthonormal alphabet (Alphabet 1). An element of  $\{U_k(nT)\}$  may then be repeated (at least once), as illustrated in FIG. 7, using a second M-ary non-cyclostationary orthonormal alphabet (Alphabet 2), interleaved, transformed to the continuous-time domain representation, filtered, amplified (not necessarily in that order) and transmitted. The repeat of an element of  $\{U_k(nT)\}$  may be performed using a different alphabet (Alphabet 2) in order to reduce or eliminate a cyclostationary feature/signature in the transmitted waveform. For at least the same reason, the at least two alphabets of FIG. 7 may be replaced by new alphabets following the transmission of a predetermined number of waveform symbols. In some embodiments, the predetermined number of waveform symbols is one. As stated earlier, a large reservoir of alphabets may be available and new alphabet choices may be made following the transmission of the predetermined number of waveform symbols and/or at predetermined TOD values.

According to some embodiments of the invention, the M-ary non-cyclostationary orthonormal alphabet waveforms may be broadband waveforms as illustrated in FIG. 8. FIG. 8 illustrates a power spectral density of a broadband waveform defining the M-ary non-cyclostationary orthonormal alphabet (such as, for example, waveform  $S_L(t)$  of FIG. 3), over frequencies of, for example, an L-band (e.g., from about 1525 MHz to about 1660.5 MHz). However, FIG. 8 is for illustrative purposes only and the power spectral density of  $S_L(t)$

and/or any other set of waveforms used to define the M-ary non-cyclostationary orthonormal alphabet may be chosen to exist over any other frequency range and/or interval(s). In some embodiments, different alphabets may be defined over different frequency ranges/intervals (this feature may provide intrinsic frequency hopping capability). As is further illustrated in FIG. 8 (second trace), certain frequency intervals that warrant protection (or additional protection) from interference, such as, for example, a GPS frequency interval, may be substantially excluded from providing frequency content for the generation of the M-ary non-cyclostationary orthonormal alphabets. It will be appreciated that the transmitter embodiment of FIG. 7 illustrates a "direct synthesis" transmitter in that the transmitter directly synthesizes a transmitted waveform, without resorting to up-conversion and/or carrier modulation. This aspect may further enhance the LPI/LPD/LPE feature(s) of a communications system.

A receiver (destination) that is configured to receive communications information from a transmitter (source) comprising the functionality of FIG. 7, may be provided with sufficient information to generate a matched filter bank corresponding to the transmitter waveform set of the M-ary alphabet  $\{U_1(nT), U_2(nT), \dots, U_M(nT)\}$ . Such a receiver may be substantially synchronized with the transmitter using GPS-derived TOD. FIG. 9 illustrates elements of such a receiver, according to exemplary embodiments of the present invention. As illustrated in FIG. 9, following front-end filtering, amplification and Analog-to-Digital and/or discrete-time (A/D) conversion of a received waveform, a matched-filter bank, comprising matched filters reflecting the TOD-dependent waveform alphabets used by the transmitter, is used for detection of information. The receiver may have information regarding what waveform alphabet the transmitter may have used as a function of TOD. As such, the receiver, operating in substantial TOD synchronism with the transmitter, may know to configure the matched-filter bank with the appropriate (TOD-dependent) matched filter components to thereby achieve optimum or near optimum signal detection. Following matched-filter detection, symbol de-interleaving and symbol repeat combination, soft decisions of a received symbol sequence may be made, followed by bit de-interleaving and bit decoding, to thereby generate an estimate of a transmitted information bit sequence.

In accordance with some embodiments of the invention, a receiver architecture, such as, for example, the receiver architecture illustrated in FIG. 9, may further configure a matched filter bank to include a "rake" matched filter architecture, to thereby resolve multipath components and increase or maximize a desired received signal energy subject to multipath fading channels. Owing to the broadband nature of the communications alphabets, in accordance with some embodiments of the invention, a significant number of multipath components may be resolvable. Rake matched filter architectures are known to those skilled in the art and need not be described further herein (see, for example, John G. Proakis, "Digital Communications," McGraw-Hill, 1983, section 7.5 starting at 479; also see R. Price and P. E. Green Jr. "A Communication Technique for Multipath Channels," Proc. IRE, Vol. 46, pp. 555-570, March 1958).

FIG. 10 illustrates an operational scenario relating to a covert communications system, in accordance with some embodiments of the invention, wherein air-to-ground, air-to-air, air-to-satellite and/or satellite-to-ground communications may be conducted. Ground-to-ground communications (not illustrated in FIG. 10) may also be conducted. Modes of communications may be, for example, point-to-point and/or point-to-multipoint. A network topology that is predeter-

mined and/or configured in an ad hoc fashion, in accordance with principles known to those skilled in the art, may be used to establish communications in accordance with any of the embodiments, of the invention and/or combinations thereof.

FIGS. 11 through 14 illustrate elements relating to a matched filter and/or a matched filter bank in accordance with exemplary embodiments of the invention, as will be appreciated by those skilled in the art. FIG. 15 further illustrates elements of a transmitter/receiver combination in accordance with some embodiments of the invention.

In some embodiments of the invention, a transmitter may be configured to selectively radiate a pseudo-random noise waveform (that may be substantially void of information) and may, for example, be Gaussian distributed, occupying a bandwidth that is substantially the same as a bandwidth occupied by a communications waveform. The transmitter may be configured to selectively radiate the pseudo-random noise waveform during periods of time during which no communications information is being transmitted. This may be used, in some embodiments, to create a substantially constant/invariant ambient/background noise floor, that is substantially independent of whether or not communications information is being transmitted, to thereby further mask an onset of communications information transmission.

It will be understood by those skilled in the art that communications systems, waveforms and/or principles described herein may also find applications in systems wherein covert-ness may not be a primary concern. Communications systems, waveforms and/or principles described herein may, for example, be used to provide short-range wireless communications (that may be broadband short-range wireless communications) in, for example, a home, office, conference and/or business environment while reducing and/or minimizing a level of interference to one or more other communications services that may be using the same, partially the same and/or near-by frequencies as the short-range communications system. Other applications of communications systems, waveforms and/or principles described herein will also occur to those skilled in the art, including, for example, radar applications and/or cellular telecommunications applications. In a cellular telecommunications application, for example, a cellular telecommunications system, in accordance with communications waveform principles described herein, may be configured, for example, as an overlay to one or more conventional cellular/PCS systems and/or one or more other systems, using the frequencies of one or more licensed and/or unlicensed bands (that may also be used by the one or more conventional cellular/PCS systems and/or the one or more other systems) to communicate with user equipment using broadband and/or Ultra Wide-Band (UWB) waveforms. The broadband and/or UWB waveforms may be non-cyclostationary and/or Gaussian-distributed, in accordance with the teachings of the present invention, to thereby reduce and/or minimize a level of interference to the one or more conventional cellular/PCS systems and/or to the one or more other systems by the overlay cellular telecommunications system and thereby allow the overlay cellular telecommunications system to reuse the available spectrum (which is also used by the one or more conventional cellular/PCS systems and/or the one or more other systems) to provide communications services to users. According to some embodiments of a cellular telecommunications application, a cellular telecommunications system that is configured to communicate with user devices using communications waveforms in accordance with the transmitter, receiver and/or waveform principles described herein, is an overlay to one or more conventional cellular/PCS systems and/or to one or more other systems and

is using the frequencies of one or more licensed and/or unlicensed bands (also being used by the one or more conventional cellular/PCS systems and/or the one or more other systems) and may be configured to communicate with the user devices preferentially using frequencies of the one or more licensed and/or unlicensed bands that are locally not used substantially and/or are locally used substantially as guardbands and/or transition bands by the one or more conventional cellular/PCS systems and/or the one or more other systems, to thereby further reduce a level of interference between the cellular telecommunications system and the one or more conventional cellular/PCS systems and/or the one or more other systems. As used herein, the terms “locally not used substantially” and/or “locally used substantially as guardbands and/or transition bands” refer to a local service area of a base station and/or group of base stations and/or access point(s) of the cellular telecommunications system. In such a service area, the cellular telecommunications system may, for example, be configured to identify frequencies that are “locally not used substantially” and/or frequencies that are “locally used substantially as guardbands and/or transition bands” by the one or more conventional cellular/PCS systems and/or the one or more other systems and preferentially use the identified frequencies to communicate bidirectionally and/or unidirectionally with user equipment thereby further reducing or minimizing a measure of interference.

Specific exemplary embodiments of the invention have been described with reference to the accompanying drawings. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete, and will fully convey the scope of the invention to those skilled in the art. It will be understood that when an element is referred to as being “connected” or “coupled” to another element, it can be directly connected or coupled to the other element or intervening elements may be present. Furthermore, “connected” or “coupled” as used herein may include wirelessly connected or coupled.

The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of the invention. As used herein, the singular forms “a,” “an” and “the” are intended to include the plural forms as well, unless expressly stated otherwise. It will be further understood that the terms “includes,” “comprises,” “including” and/or “comprising,” when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof.

Unless otherwise defined, all terms (including technical and scientific terms) used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. It will be further understood that terms, such as those defined in commonly used dictionaries, should be interpreted as having a meaning that is consistent with their meaning in the context of the relevant art and the present disclosure, and will not be interpreted in an idealized or overly formal sense unless expressly so defined herein.

It will be understood that although the terms first and second may be used herein to describe various elements, these elements should not be limited by these terms. These terms are only used to distinguish one element from another element. As used herein, the term “and/or” includes any and

## 11

all combinations of one or more of the associated listed items. The symbol “/” is also used as a shorthand notation for “and/or”.

The present invention was described above with reference to block diagrams of methods, apparatus (systems), components and/or computer program products according to embodiments of the invention. It is understood that a given block of the block diagrams, and combinations of blocks in the block diagrams may be implemented by computer program instructions. These computer program instructions may be provided to a processor of a general purpose computer, special purpose computer, such as a digital signal processor, and/or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer and/or other programmable data processing apparatus, create means for implementing the functions/acts specified in the block diagrams block or blocks.

These computer program instructions may also be stored in a computer-readable memory that can direct a computer or other programmable data processing apparatus to function in a particular manner, such that the instructions stored in the computer-readable memory produce an article of manufacture including instructions which implement the function/act specified in the block diagram block or blocks.

The computer program instructions may also be loaded onto a computer or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer or other programmable apparatus to produce a computer-implemented process such that the instructions which execute on the computer or other programmable apparatus provide steps for implementing the functions/acts specified in the block diagram block or blocks.

In the specification and the Figures thereof, there have been disclosed embodiments of the invention and, although specific terms are employed, they are used in a generic and descriptive sense only and not for purposes of limitation; the scope of the invention being set forth in the following claims.

What is claimed is:

1. A communications method comprising:  
mapping by a transmitter information into a baseband waveform; and  
varying a spectral content of the baseband waveform, without resorting to chipping, by using for said mapping first and second waveform elements that differ therebetween in bandwidth.
2. The communications method according to claim 1, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent one another; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.
3. The communications method according to claim 1, wherein said mapping is preceded by:  
processing a bit sequence to obtain the information.
4. The communications method according to claim 1, wherein said varying is followed by:  
further processing the baseband waveform, the spectral content of which was varied; and  
wirelessly transmitting the information using the baseband waveform that was further processed.

## 12

5. The communications method according to claim 1, wherein said first and second waveform elements that differ therebetween in bandwidth comprise respective first and second spectral contents that partially overlap therebetween.

6. The communications method according to claim 5, wherein the first and second waveform elements are used over adjacent transmit/receive intervals.

7. The communications method according to claim 1, wherein said first and second waveform elements that differ therebetween in bandwidth comprise respective first and second spectral contents that are devoid of overlap therebetween.

8. The communications method according to claim 7, wherein the first and second waveform elements are used over adjacent transmit/receive intervals.

9. The communications method according to claim 1, wherein said first and second waveform elements are separated therebetween by a range of frequencies that is devoid of the information that was mapped into the baseband waveform.

10. The communications method according to claim 1, further comprising:

- distributing a frequency content of the baseband waveform over first and second frequency intervals that are separated therebetween by a third frequency interval; and
- refraining from distributing the frequency content over the third frequency interval.

11. The communications method according to claim 1, wherein the baseband waveform comprises a sequence of discrete-time waveforms; wherein a first waveform of the sequence of discrete-time waveforms comprises a first duration; and wherein a second waveform of the sequence of discrete-time waveforms comprises a second duration that differs from the first duration.

12. The communications method according to claim 1, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent transmit/receive intervals; and

- wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

13. The communications method according to claim 1, wherein the transmitter comprises a mobile transmitter that is stationary relative to the Earth.

14. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; wherein the transmitter comprises a mobile transmitter that is stationary relative to the Earth; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the mobile transmitter while the mobile transmitter remains stationary relative to the Earth.

15. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform, and further comprises:

- excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling inter-

13

vals, that are adjacent therebetween, responsive to a transmission of the transmitter and subject to said excluding certain frequency intervals responsive to an interference concern.

16. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and

wherein said mapping by a transmitter information into a baseband waveform comprises:

evaluating a frequency content;

forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency.

17. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping by a transmitter information into a baseband waveform comprises:

forming by the transmitter a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and

mapping by the transmitter the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;

wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol.

18. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency;

wherein the transmitter comprises a mobile transmitter that is stationary relative to the Earth;

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the mobile transmitter while the mobile transmitter remains stationary relative to the Earth;

wherein said varying a spectral content of the baseband waveform further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the transmitter and subject to said excluding certain frequency intervals responsive to an interference concern;

wherein said mapping by a transmitter information into a baseband waveform comprises:

evaluating a frequency content;

forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency; and wherein said mapping by a transmitter information into a baseband waveform further comprises:

forming by the transmitter a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and mapping by the transmitter the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;

wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of

14

which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol.

19. The communications method according to claim 1, wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals that are adjacent therebetween.

20. The communications method according to claim 1, further comprising:

varying said spectral content of the baseband waveform, without resorting to chipping, by using for said mapping said first and second waveform elements further differing therebetween in frequency range while avoiding certain frequency intervals from being included in said spectral content responsive to an interference concern; transmitting by said transmitter said first and second waveform elements that differ therebetween in bandwidth and differ therebetween in frequency range over respective first and second transmit/receive time intervals that are adjacent therebetween; and

transmitting by said transmitter cyclostationary waveforms;

wherein said transmitter is a transmitter of a cellular telecommunications system wherein covertness is not a primary concern;

wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and

wherein said information that is mapped into said baseband waveform comprises a bit sequence that is operated upon by said transmitter to thereby form an information symbol sequence which is then mapped by said transmitter into said baseband waveform.

21. The communications method according to claim 20, wherein said first and second waveform elements that differ therebetween in bandwidth and differ therebetween in frequency range vary and are orthogonal therebetween over a first time span; and vary and are non-orthogonal therebetween over a second time span.

22. The communications method according to claim 1, further comprising:

generating by said transmitter cyclostationary waveforms; and

transmitting by said transmitter cyclostationary waveforms;

wherein said mapping by a transmitter information into a baseband waveform comprises:

mapping by the transmitter an input bit sequence  $\{b\}$  into an information symbol sequence  $\{I_k\}$  and mapping by the transmitter the information symbol sequence  $\{I_k\}$  into a discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$ ; wherein  $k$  denotes values of discrete time;  $k=1, 2, \dots$ ; wherein for each value of  $k$ ,  $n$  takes on a plurality of integer values corresponding to a respective plurality of values of the discrete-time, cyclostationary, baseband waveform  $U_k(nT)$ ;  $T>0$ ; and

wherein said mapping by the transmitter the information symbol sequence  $\{I_k\}$  into a discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$ , comprises: using first and second discrete-time, cyclostationary, baseband waveform elements, over respective first and second successive and adjacent values of  $k$ ; said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first

15

and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof; and

transmitting by said transmitter said discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$  following further processing thereof by the transmitter; wherein said transmitter is a transmitter of a cellular telecommunications system wherein covertness is not a primary concern; and wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency.

23. The communications method according to claim 22, wherein said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof, are orthogonal therebetween.

24. The communications method according to claim 23, wherein a time duration that is associated with said discrete-time, cyclostationary, baseband waveform  $U_k(nT)$  varies over different values of  $k$ .

25. The communications method according to claim 22, wherein said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof, are non-orthogonal therebetween.

26. The communications method according to claim 25, wherein a time duration that is associated with said discrete-time, cyclostationary, baseband waveform  $U_k(nT)$  varies over different values of  $k$ .

27. A communications method comprising:  
processing by a receiver a waveform that comprises a variable spectral content and is devoid of chipping, by using by the receiver first and second waveform elements that differ therebetween in bandwidth; and mapping the waveform that was processed into an information sequence.

28. The communications method according to claim 27, wherein said processing by a receiver a waveform is preceded by wirelessly receiving at the receiver a measure of the waveform and wherein said processing by a receiver a waveform further comprises:

using by the receiver a Fourier transform operation;  
synchronizing by the receiver said first and second waveform elements that differ therebetween in bandwidth with said variable spectral content; and detecting an information content of said variable spectral content by using said first and second waveform elements that differ therebetween in bandwidth.

29. The communications method according to claim 28, wherein said synchronizing by the receiver is preceded by wirelessly receiving at the receiver synchronization information.

30. The communications method according to claim 29, wherein said processing by a receiver a waveform further comprises:

using the synchronization information that is wirelessly received at the receiver in said using first and second waveform elements that differ therebetween in bandwidth.

31. The communication method according to claim 27, wherein said mapping is followed by:  
generating a bit sequence from said information sequence.

16

32. The communications method according to claim 27, wherein the receiver comprises a mobile receiver that is stationary relative to the Earth.

33. The communications method according to claim 27, wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using by the receiver first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

34. A communications method comprising:  
mapping information that is to be transmitted into a baseband waveform;

varying a spectral content of the baseband waveform, without resorting to chipping, by using for said mapping first and second waveform elements that differ therebetween in spectral content;

processing a waveform that comprises a variable spectral content and is devoid of chipping by using first and second waveform elements that differ therebetween in bandwidth; and

mapping the waveform that was processed into a received information sequence.

35. The communications method according to claim 34, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent one another; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

36. The communications method according to claim 34, wherein said mapping information that is to be transmitted into a baseband waveform is preceded by:

processing a bit sequence to obtain the information that is to be transmitted.

37. The communications method according to claim 34, wherein said varying is followed by:

further processing the baseband waveform, the spectral content of which was varied; and

wirelessly transmitting said information that is to be transmitted using the baseband waveform that was further processed.

17

38. The communications method according to claim 34, wherein said first and second waveform elements that differ therebetween in spectral content further differ therebetween in bandwidth.

39. The communications method according to claim 38, wherein the first and second waveform elements that differ therebetween in spectral content and further differ therebetween in bandwidth are used over adjacent transmit/receive intervals.

40. The communications method according to claim 34, wherein said first and second waveform elements that differ therebetween in spectral content differ therebetween in a frequency range that is being used to provide said spectral content.

41. The communications method according to claim 40, wherein the first and second waveform elements that differ therebetween in spectral content and differ therebetween in said frequency range that is being used to provide said spectral content are used over adjacent transmit/receive intervals.

42. The communications method according to claim 34, wherein said first and second waveform elements that differ therebetween in spectral content are separated therebetween by a range of frequencies that is devoid of the information that was mapped into the baseband waveform.

43. The communications method according to claim 34, further comprising:

distributing a frequency content of the baseband waveform over first and second frequency intervals that are separated therebetween by a third frequency interval; and refraining from distributing the frequency content over the third frequency interval.

44. The communications method according to claim 34, wherein the baseband waveform comprises a sequence of discrete-time waveforms; wherein a first waveform of the sequence of discrete-time waveforms comprises a first duration; and

wherein a second waveform of the sequence of discrete-time waveforms comprises a second duration that differs from the first duration.

45. The communications method according to claim 34, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent transmit/receive intervals; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

46. The communications method according to claim 34, wherein said processing a waveform comprises:

synchronizing said first and second waveform elements that differ therebetween in bandwidth with said variable spectral content; and

detecting said variable spectral content by using said first and second waveform elements that differ therebetween in bandwidth.

47. The communications method according to claim 34, wherein said processing a waveform comprises: using a Fourier transform operation.

48. The communications method according to claim 34, wherein said processing a waveform is preceded by: wirelessly receiving said waveform.

49. The communication method according to claim 34, wherein said mapping the waveform is followed by: generating a bit sequence from said received information sequence.

50. The communications method according to claim 34, wherein said mapping information, varying a spectral con-

18

tent, processing a waveform, and mapping the waveform are performed by a transceiver comprising a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; said transceiver comprising a mobile transceiver that is stationary relative to the Earth; and

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the mobile transceiver while the mobile transceiver remains stationary relative to the Earth; and

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

51. The communications method according to claim 34, wherein said mapping information, varying a spectral content, processing a waveform, and mapping the waveform are performed by a transceiver; wherein the transceiver comprises a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform, and further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the transceiver and subject to said excluding certain frequency intervals responsive to an interference concern;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said wave-

19

form that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

52. The communications method according to claim 34, wherein said mapping information, varying a spectral content, processing a waveform, and mapping the waveform are performed by a transceiver comprising a transmitter and a receiver; and wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and

wherein said mapping information that is to be transmitted into a baseband waveform comprises:

evaluating a frequency content;

forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

53. The communications method according to claim 34, wherein said mapping information, varying a spectral content, processing a waveform, and mapping the waveform are performed by a transceiver comprising a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping information that is to be transmitted into a baseband waveform comprises:

forming by the transmitter a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and mapping by the transmitter the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;

wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends

20

upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol; wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

54. The communications method according to claim 34, wherein said mapping information, varying a spectral content, processing a waveform, and mapping the waveform are performed by a transceiver comprising a transmitter and a receiver;

wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency;

wherein the transceiver comprises a mobile transceiver that is stationary relative to the Earth;

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the mobile transceiver while the mobile transceiver remains stationary relative to the Earth;

wherein said varying a spectral content of the baseband waveform further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission of the transceiver and subject to said excluding certain frequency intervals responsive to an interference concern;

wherein said mapping information that is to be transmitted into a baseband waveform comprises:

evaluating a frequency content;

forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency;

wherein said mapping information that is to be transmitted into a baseband waveform further comprises:

forming by the transmitter a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and mapping by the transmitter the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;

wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of

21

which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol; wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

55. The communications method according to claim 34, wherein said mapping information, varying a spectral content, processing a waveform, and mapping the waveform are performed by a transceiver comprising a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals that are adjacent therebetween; and

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

56. A communications system comprising:

a processor that is configured to perform operations comprising:

mapping information into a baseband waveform; and

22

varying a spectral content of the baseband waveform, without resorting to chipping, by using for said mapping first and second waveform elements that differ therebetween in bandwidth.

57. The communications system according to claim 56, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent one another; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

58. The communications system according to claim 56, wherein said processor is further configured to process a bit sequence in order to obtain the information.

59. The communications system according to claim 56, wherein said processor is configured to further process the baseband waveform, the spectral content of which was varied, following said varying; and

wherein the communication system further comprises a transmitter that is configured to perform operations comprising wirelessly transmitting the information using the baseband waveform that was further processed.

60. The communications system according to claim 56, wherein said first and second waveform elements that differ therebetween in bandwidth comprise respective first and second spectral contents that partially overlap therebetween.

61. The communications system according to claim 56, wherein the first and second waveform elements are used over adjacent transmit/receive intervals.

62. The communications system according to claim 56, wherein said first and second waveform elements that differ therebetween in bandwidth comprise respective first and second spectral contents that are devoid of overlap therebetween.

63. The communications system according to claim 62, wherein the first and second waveform elements are used over adjacent transmit/receive intervals.

64. The communications system according to claim 56, wherein said first and second waveform elements are separated therebetween by a range of frequencies that is devoid of the information that was mapped into the baseband waveform.

65. The communications system according to claim 56, wherein the operations further comprise:

distributing a frequency content of the baseband waveform over first and second frequency intervals that are separated therebetween by a third frequency interval; and refraining from distributing the frequency content over the third frequency interval.

66. The communications system according to claim 56, wherein the baseband waveform comprises a sequence of discrete-time waveforms; wherein a first waveform of the sequence of discrete-time waveforms comprises a first duration; and

wherein a second waveform of the sequence of discrete-time waveforms comprises a second duration that differs from the first duration.

67. The communications system according to claim 56, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from

23

the first spectral content; wherein the first and second time intervals are adjacent transmit/receive intervals; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

68. The communications system according to claim 56, wherein said processor is part of a mobile transmitter that is stationary relative to the Earth; wherein said mobile transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the mobile transmitter while the mobile transmitter remains stationary relative to the Earth.

69. The communications system according to claim 56, wherein said processor is part of a transmitter; wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform, and further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the transmitter while subject to said excluding certain frequency intervals responsive to an interference concern.

70. The communications system according to claim 56, wherein said processor is part of a transmitter; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping information into a baseband waveform comprises:

evaluating a frequency content;  
forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and  
using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency.

71. The communications system according to claim 56, wherein said processor is part of a transmitter; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping information into a baseband waveform comprises:

forming a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and  
mapping the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;  
wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol.

72. The communications system according to claim 56, wherein said processor is part of a mobile transmitter that is stationary relative to the Earth; wherein said mobile transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency;

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmis-

24

sion by the mobile transmitter while the mobile transmitter remains stationary relative to the Earth;  
wherein said varying a spectral content of the baseband waveform further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the transmitter while subject to said excluding certain frequency intervals responsive to an interference concern;

wherein said mapping information into a baseband waveform comprises:

evaluating a frequency content;  
forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency;

wherein said mapping information into a baseband waveform further comprises:

forming a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and  
mapping the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;  
wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol.

73. The communications system according to claim 56, wherein said processor is part of a transmitter that is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals that are adjacent therebetween.

74. The communications system according to claim 56, wherein said processor is part a transmitter and is further configured to perform operations comprising:

varying said spectral content of the baseband waveform, without resorting to chipping, by using for said mapping said first and second waveform elements further differing therebetween in frequency range while excluding certain frequency intervals from being included in said spectral content responsive to an interference concern; and

providing to said transmitter, and transmitting by said transmitter, said first and second waveform elements that differ therebetween in bandwidth and differ therebetween in frequency range over respective first and second transmit/receive time intervals that are adjacent therebetween;

wherein said transmitter is configured to transmit cyclostationary waveforms and is a transmitter of a cellular telecommunications system wherein covertness is not a primary concern;

wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and

wherein said information that is mapped into said baseband waveform comprises a bit sequence that is operated upon by said processor to thereby form an information symbol sequence which is then mapped by said processor into said baseband waveform.

75. The communications system according to claim 74, wherein said first and second waveform elements that differ

25

therebetween in bandwidth and differ therebetween in frequency range vary and are orthogonal therebetween over a first time span; and vary and are non-orthogonal therebetween over a second time span.

76. The communications system according to claim 56, further comprising:

a transmitter that is connected to said processor;  
wherein the processor is configured to perform further operations comprising:

generating discrete-time, cyclostationary, baseband waveforms;

wherein said mapping information into a baseband waveform comprises:

mapping by the processor an input bit sequence  $\{b\}$  into an information symbol sequence  $\{I_k\}$  and mapping by the processor the information symbol sequence  $\{I_k\}$  into a discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$ ; wherein  $k$  denotes values of discrete time;  $k=1, 2, \dots$ ; wherein for each value of  $k$ ,  $n$  takes on a plurality of integer values corresponding to a respective plurality of values of the discrete-time, cyclostationary, baseband waveform  $U_k(nT)$ ;  $T>0$ ; and wherein said mapping by the processor the information symbol sequence  $\{I_k\}$  into a discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$ , comprises:

using first and second discrete-time, cyclostationary, baseband waveform elements, over respective first and second successive and adjacent values of  $k$ ; said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof;

providing by the processor said discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$  to said transmitter for further processing and transmission thereof; and

transmitting by said transmitter said discrete-time, cyclostationary, baseband waveform sequence  $\{U_k(nT)\}$  following said further processing thereof;

wherein said transmitter is a transmitter of a cellular telecommunications system wherein covertness is not a primary concern; and

wherein said transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency.

77. The communications system according to claim 76, wherein said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof, are orthogonal therebetween.

78. The communications system according to claim 77, wherein a time duration that is associated with said discrete-time, cyclostationary, baseband waveform  $U_k(nT)$  varies over different values of  $k$ .

79. The communications system according to claim 76, wherein said first and second discrete-time, cyclostationary, baseband waveform elements differing therebetween in respective first and second frequency ranges that provide respective first and second frequency contents thereto and further differing therebetween in respective first and second bandwidths thereof, are non-orthogonal therebetween.

26

80. The communications system according to claim 79, wherein a time duration that is associated with said discrete-time, cyclostationary, baseband waveform  $U_k(nT)$  varies over different values of  $k$ .

81. A communications system comprising:

a processor that is configured to perform operations comprising:

processing a waveform that comprises a variable spectral content and is devoid of chipping by using first and second waveform elements that differ therebetween in bandwidth; and

mapping the waveform that was processed into an information sequence.

82. The communications system according to claim 81, further comprising a receiver that is configured to wirelessly receive a measure of the waveform; and wherein said processor is further configured to perform a Fourier transform operation, synchronize said first and second waveform elements that differ therebetween in bandwidth with said variable spectral content and to detect an information content of said variable spectral content by using said first and second waveform elements that differ therebetween in bandwidth.

83. The communications system according to claim 82, wherein said receiver is further configured to wirelessly receive synchronization information.

84. The communications system according to claim 83, wherein said processor is further configured to use the synchronization information that is wirelessly received by the receiver in said using first and second waveform elements that differ therebetween in bandwidth.

85. The communication system according to claim 81, wherein said processor is further configured to generate a bit sequence from said information sequence.

86. The communications system according to claim 81, wherein said processor is part of a receiver;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

87. A communications system comprising:

a processor that is configured to perform operations comprising:

mapping information that is to be transmitted into a baseband waveform;

27

varying a spectral content of the baseband waveform, without resorting to chipping, by using for said mapping first and second waveform elements that differ therebetween in spectral content;

processing a waveform that comprises a variable spectral content and is devoid of chipping by using first and second waveform elements that differ therebetween in bandwidth; and

mapping the waveform that was processed into a received information sequence.

88. The communications system according to claim 87, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent one another; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

89. The communications system according to claim 87, wherein said processor is further configured to process a bit sequence in order to obtain the information that is to be transmitted.

90. The communications system according to claim 87, wherein the processor is configured to further process the baseband waveform, the spectral content of which was varied, following said varying; and wherein the communication system further comprises a transmitter that is configured to perform operations comprising wirelessly transmitting said information that is to be transmitted using the baseband waveform that was further processed.

91. The communications system according to claim 87, wherein said first and second waveform elements that differ therebetween in spectral content further differ therebetween in bandwidth.

92. The communications system according to claim 91, wherein the first and second waveform elements that differ therebetween in spectral content and further differ therebetween in bandwidth are used over adjacent transmit/receive intervals.

93. The communications system according to claim 87, wherein said first and second waveform elements that differ therebetween in spectral content differ therebetween in a frequency range that is being used to provide said spectral content.

94. The communications system according to claim 93, wherein the first and second waveform elements that differ therebetween in spectral content and differ therebetween in said frequency range that is being used to provide said spectral content are used over adjacent transmit/receive intervals.

95. The communications system according to claim 87, wherein said first and second waveform elements that differ therebetween in spectral content are separated therebetween by a range of frequencies that is devoid of the information that was mapped into the baseband waveform.

96. The communications system according to claim 87, wherein the processor is further configured to distribute a frequency content of the baseband waveform over first and second frequency intervals that are separated therebetween by a third frequency interval; and to refrain from distributing the frequency content over the third frequency interval.

97. The communications system according to claim 87, wherein the baseband waveform comprises a sequence of discrete-time waveforms; wherein a first waveform of the sequence of discrete-time waveforms comprises a first dura-

28

tion; and wherein a second waveform of the sequence of discrete-time waveforms comprises a second duration that differs from the first duration.

98. The communications system according to claim 87, wherein over a first time interval the baseband waveform comprises a first discrete-time waveform comprising a first spectral content; wherein over a second time interval the baseband waveform comprises a second discrete-time waveform comprising a second spectral content that differs from the first spectral content; wherein the first and second time intervals are adjacent transmit/receive intervals; and wherein the first and second discrete-time waveforms are used to transmit respective first and second information over said first and second time intervals, respectively.

99. The communications system according to claim 87, wherein said processor is further configured to synchronize said first and second waveform elements that differ therebetween in bandwidth with said variable spectral content; and to detect an information content of said variable spectral content by using said first and second waveform elements that differ therebetween in bandwidth.

100. The communications system according to claim 87, wherein said processing a waveform comprises: using a Fourier transform operation.

101. The communications system according to claim 87, further comprising a receiver; wherein said processing a waveform is preceded by wirelessly receiving a measure of said waveform by the receiver.

102. The communications system according to claim 101, wherein the receiver comprises a wireless receiver.

103. The communication system according to claim 87, wherein said processor is further configured to generate a bit sequence from said received information sequence.

104. The communications system according to claim 87, wherein said processor is part of a mobile transceiver that is stationary relative to the Earth; wherein the mobile transceiver comprises a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the mobile transceiver while the mobile transceiver remains stationary relative to the Earth;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

29

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

**105.** The communications system according to claim **87**, wherein said processor is part of a transceiver; wherein the transceiver comprises a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform, and further comprises:

excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the transmitter and subject to said excluding certain frequency intervals responsive to an interference concern;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

**106.** The communications system according to claim **87**, wherein said processor is part of a transceiver comprising a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping information that is to be transmitted into a baseband waveform comprises:

evaluating a frequency content;

forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and

using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said wave-

30

form that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

**107.** The communications system according to claim **87**, wherein said processor is part of a transceiver; wherein the transceiver comprises a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said mapping information that is to be transmitted into a baseband waveform comprises:

forming a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and

mapping the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;

wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol;

wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and

wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:

excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:

forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.

**108.** The communications system according to claim **87**, wherein said processor is part of a transceiver that comprises a transmitter and a receiver;

wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency;

wherein the transceiver comprises a mobile transceiver that is stationary relative to the Earth; and

wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the mobile transceiver while the mobile transceiver remains stationary relative to the Earth;

31

wherein said varying a spectral content of the baseband waveform further comprises:  
 excluding certain frequency intervals responsive to an interference concern, and varying said bandwidth of the baseband waveform over two successive signaling intervals, that are adjacent therebetween, responsive to a transmission by the transmitter and subject to said excluding certain frequency intervals responsive to an interference concern;  
 wherein said mapping information that is to be transmitted into a baseband waveform comprises:  
 evaluating a frequency content;  
 forming a desired spectrum shape responsive to the frequency content and responsive to an interference concern; and  
 using a time-domain representation of the desired spectrum shape to modulate the single carrier frequency;  
 wherein said mapping information that is to be transmitted into a baseband waveform further comprises:  
 forming a sequence of information symbols  $\{I_k\}$  responsive to an information bit sequence; and  
 mapping the sequence of information symbols  $\{I_k\}$  onto a waveform sequence  $\{U_k\}$ ;  
 wherein a Fourier transform of the waveform sequence  $\{U_k\}$  comprises a plurality of frequencies each one of which comprises a non-zero amplitude that depends upon an information symbol of said sequence of information symbols  $\{I_k\}$  but is not the information symbol;  
 wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and  
 wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:  
 excluding certain frequency intervals from said first and second waveform elements, and using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;

32

wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:  
 forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.  
**109.** The communications system according to claim 87, wherein said processor is part of a transceiver; wherein the transceiver comprises a transmitter and a receiver; wherein the transmitter is devoid of a plurality of modulators and comprises a single modulator modulating a single carrier frequency; and wherein said varying a spectral content of the baseband waveform comprises varying a bandwidth of the baseband waveform over two successive signaling intervals that are adjacent therebetween;  
 wherein said waveform that comprises a variable spectral content and is devoid of chipping comprises a variable bandwidth that varies over first and second successive signaling intervals thereof that are adjacent therebetween; and  
 wherein said using first and second waveform elements that differ therebetween in bandwidth comprises:  
 using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween;  
 wherein said using said first and second waveform elements that differ therebetween in bandwidth over said first and second successive signaling intervals, respectively, in order to receive said waveform that comprises the variable bandwidth over the first and second successive signaling intervals thereof that are adjacent therebetween comprises:  
 forming first and second Fourier transforms over said first and second successive signaling intervals, respectively.
